Ranks

When comparing poker hands, we need to establish their ranks, which is one of the following:

- Nothing. No cards of the same value, at least two suits, and no consecutive order.
- One pair. Two cards with the same value
- Two pairs. Two pairs of cards with the same value.
- Three of a kind. Three cards with the same value.
- Straight. All card values in consecutive order.
- Flush. All cards of the same suit.
- Full House. Three of a kind and a pair.
- Four of a kind. Four cards with the same value.
- Straight Flush. A straight and a flush.
- Royal Flush. A straight flush with ace as its highest cards.

Technically, we do not need the royal flush since all straight flushes are compared with regards to their highest cards. Thereby follows that a straight flush with an ace outranks all straight flushes without aces.

Comparison

When comparing two hands, we look into their ranks, max values, min values, and rest values.

- Rank
 - One of the ten ranks described above, in ascending order. Royal flush holds the highest rank, and nothing holds the lowest rank.
- Max value
 - Royal flush, straight flush, and straight: the value of the highest cards.
 - Full house and three of a kind: the value of three of a kind.
 - Two pairs: the value of the highest pair.
 - One pair: the value of the pair.
- Min value
 - Two pairs: the value of the lowest pair.
- Rest values
 - Flush and nothing: the values of all the cards, in descending order.
 - Two pairs: the value of the remaining card, that is not a part of any of the pairs.
 - One pair: the values of the remaining three cards, that is not part of the pair, in descending order.

The comparison of two hands is performed as follows:

1. If the hands hold different ranks, the hand with highest rank wins.
2. If they hold the same rank, but different max values, the hand with the largest max value wins.
 - Always applies to four of a kind, full house, and three of a kind, since two hands cannot hold four or three cards with same value. Note that when comparing two full houses, we compare the values of the three of a kind, even though the values of the pairs may be higher.
 - May apply to two pairs and one pair, since two hands may hold pairs of the same values.
 - Never applies to flush or nothing, the max value is always zero.

3. If they hold the same rank and max value, but different min values, the hand with the highest min value wins.
 - Only applies when comparing two hands of two pairs, where the highest pairs are equal. If the lowest pairs are different, the hand with the highest lowest pair wins.
 - Is always zero for all other hands.
4. If they hold the same rank, max value, and min value, the hand with the highest cards among the remaining cards wins.
 - Flush and nothing: the remaining cards are made by all the cards of the hands. The cards are compared in descending order, where the highest card wins.
 - Two pairs: the remaining cards are made up by the fifth card that is not a part of the pairs. The hand with the highest card wins.
 - One pair: the remaining cards are made by the three cards that are not part of the pair. The cards are compared in descending order, where the highest card wins.
 - Always empty for all other hands.

The following table sums up the features when comparing two hands.

Rank	Max Value	Min Value	Rest Values
Royal flush	The value of the highest card	Always zero	Always empty
Stright flush	The value of the highest card	Always zero	Always empty
Four of a kind	The value of the four cards of a kind	Always zero	Always empty
Full house	The value of the three cards of a kind	Always zero	Always empty
Flush	Always zero	Always zero	The values of all the cards
Straight	The value of the highest card	Always zero	Always empty
Three of a kind	The value of the three cards of a kind	Always zero	Always empty
Two pairs	The value of the highest pair	The value of the lowest pair	The values of the card not in the two pairs
One pair	The value of the pair	Always zero	The values of the three cards not in the pair
Nothing	Always zero	Always zero	The values of all the cards

In case of flush or nothing we need to compare all the cards of the hands, since their four highest cards may hold the same values.

Code

The code is divided into the following source files:

Card	Holds code for a single card.
Poker	Holds code for a hand of five cards, and the comparison of two hands.
Result	Holds the result of the comparison: Win, Tie, or Lose.
Error	Holds error messages to be panicked.
Main	Creates and displays hands.
Main Test	Hold test cases for the comparison of two hands.

Card

The card file handles a card, which is made up by a value and a suit.

card/card.go

```
package card
```

A card can hold the values between two and ace, inclusive.

```
const (
    Jack int = iota + 11
    Queen
    King
    Ace
)
```

The suit of a card is clubs, diamonds, hearts, and spades.

```
const (
    Clubs int = iota
    Diamonds
    Hearts
    Spades
)
```

A card holds a value and a suit, which are both represented by integer values.

```
type Card struct {
    Value int
    Suit int
}
```

The **New** function returns a new card with the given value and suit.

```
func New(value int, suit int) Card {
    return Card{value, suit}
}
```

The **LessThan** and **GreaterThan** methods are called when cards are inserted in the cards list, in ascending or descending order. They return true if the left card is less than or greater than the right card, respectively.

```
func (leftCard Card) LessThan(rightCard Card) bool {
    return leftCard.Value < rightCard.Value
}

func (leftCard Card) GreaterThan(rightCard Card) bool {
    return leftCard.Value > rightCard.Value
}
```

Finally, the **String** method returns a string with the value and the suit of the card written in plain text.

```
func (card Card) String() string {
    valueArray := [...]string{"Two", "Three", "Four", "Five", "Six", "Seven",
                               "Eight", "Nine", "Ten", "Jack", "Queen", "King", "Ace"}
    suitArray := [...]string{"Clubs", "Diamonds", "Hearts", "Spades"}
    return valueArray[card.Value - 2] + " of " + suitArray[card.Suit]
}
```

Hand

The source file of the hand holds code for creating a hand, analyzing the card, ranking the hand, comparing two hands, and converting the hand into a string.

poker/poker.go

```
package poker
```

```
import (  
    "strings"  
    "strconv"  
    "container/list"  
    "card"  
    "result"  
    "error"  
)
```

The rank of a hand may differ from nothing to royal flush.

```
const (  
    Nothing int = iota  
    OnePair  
    TwoPairs  
    ThreeOfAKind  
    Straight  
    Flush  
    FullHouse  
    FourOfAKind  
    StraightFlush  
    RoyalFlush  
)
```

The **ComparableHand** interface makes sure that all structures implementing it hold the **CompareWith** method.

```
type ComparableHand interface {  
    CompareWith(compareTo ComparableHand) (theResult int)  
}
```

A hand holds a list of cards, a rank, a max and min value, a map of the cards, and a list of rest values.

```
type hand struct {  
    m_cardList *list.List  
    m_rank, m_maxValue, m_minValue int  
    m_map map[int]*list.List  
    m_restValues *list.List  
}
```

The **NewHand** function creates and returns a new hand by analyzing the text, analyzing the cards, and setting the rank.

```
func NewHand(text string) ComparableHand {  
    var newHand hand  
    (&newHand).analyzeText(text)  
    (&newHand).analyzeCards()  
    (&newHand).setRankOfHand()  
    return newHand  
}
```

The **analyzeText** method extracts the value and suit of each card in the text, and creates and adds the cards to the card list of the hand.

```
func (handPtr *hand) analyzeText(text string) {
    handPtr.m_cardList = list.New()
    cardTextArray := strings.Split(text, " ")
```

If there are not five cards in the text, we report an error.

```
    if len(cardTextArray) != 5 {
        error.InvalidNumberOfCards(len(cardTextArray))
    }
```

We iterate through the cards of the text.

```
    for _, cardText := range cardTextArray {
```

If a card is not represented by two character, we report an error.

```
        if len(cardText) != 2 {
            error.InvalidLengthOfCardText(cardText)
        }
```

We extract the character representing the value, and convert it to upper case.

```
        valueChar := string(cardText[0])
        valueCharUpper := strings.ToUpper(valueChar)

        const valueText string = "23456789TJQKA"
        var value int
```

If the character does not represent a card value, we report an error.

```
        if strings.Contains(valueText, valueCharUpper) {
            value = strings.Index(valueText, valueCharUpper) + 2
        } else {
            error.InvalidCardValue(valueChar)
        }
```

We extract the character representing the suit, and convert it to upper case.

```
        suitChar := string(cardText[1])
        suitCharUpper := strings.ToUpper(suitChar)

        suitMap := map[string]int{"C": card.Clubs, "D": card.Diamonds,
                                   "H": card.Hearts, "S": card.Spades}
        suit, exists := suitMap[suitCharUpper]
```

If the character does not represent a card suit, we report an error.

```
        if !exists {
            error.InvalidCardSuit(suitChar)
        }
```

Now we are ready to create a new card, and insert it at its proper position in the card list.

```
        newCard := card.New(value, suit)
        inserted := false

        for iterator := handPtr.m_cardList.Front(); iterator != nil;
            iterator = iterator.Next() {
            card := iterator.Value.(card.Card)
```

If the card is already present in the hand, we report an error.

```
if card == newCard {
    error.CardOccursTwice(card)
}
```

When we find a card in the card list that is smaller (its value is lower) than the new card, we insert the new card at that position.

```
if newCard.GreaterThan(card) {
    handPtr.m_cardList.InsertBefore(newCard, iterator)
    inserted = true
    break
}
}
```

If we have iterated through the card list without inserting the new card, we add it at the end of the card list.

```
if !inserted {
    handPtr.m_cardList.PushBack(newCard)
}
}
```

The **analyzeCards** method iterates through the cards and, for each card, count the number of times the card value occurs in the hand. In this way, we catch all four of a kind, three of a kind, and pairs.

```
func (handPtr *hand) analyzeCards() {
    handPtr.m_map = make(map[int]*list.List)
```

For instance, **{2: [12], 3: [10]}** is a full house with two queens and three tens, **{2: [10, 8], 1: [6]}** is two pairs of tens and eights, and one six. The value of the highest pair always comes first in the list, since the cards list was created in that order from the beginning. Note that we do not look into the suits of the cards in this method. The only time the suits is of interest is when comparing two flushes.

```
for outerIterator := handPtr.m_cardList.Front(); outerIterator != nil;
    outerIterator = outerIterator.Next() {
    outerCard := outerIterator.Value.(card.Card)
    count := 0
```

For each card, we iterate the cards again and count how many times its value occurs in the hand.

```
for innerIterator := handPtr.m_cardList.Front(); innerIterator != nil;
    innerIterator = innerIterator.Next() {
    innerCard := innerIterator.Value.(card.Card)

    if outerCard.Value == innerCard.Value {
        count++
    }
}
```

When we have counted the number of cards with the same value, we look up its list in the map. If there is no list, we create a new list.

```
listPtr, exists := handPtr.m_map[count]
if !exists {
    listPtr = list.New()
}
```

We add the value of the cards to the list, if it is not already present in the list, and add the list to the map.

```
    if !containsValueInList(listPtr, outerCard.Value) {
        listPtr.PushBack(outerCard.Value)
    }

    handPtr.m_map[count] = listPtr
}
}
```

The **containsValueInList** method returns true if the value is a member of the list.

```
func containsValueInList(listPtr *list.List, value interface{}) bool {
    for iterator := listPtr.Front(); iterator != nil;
        iterator = iterator.Next() {
        if iterator.Value == value {
            return true
        }
    }

    return false
}
```

The **setRankOfHand** method sets the rank, max and min value, and the rest values of the hand by calling a sequence of methods, beginning with the royal flush that holds the highest rank.

```
func (handPtr *hand) setRankOfHand() {
```

In case of a royal flush we do not have to do anything, except store the rank.

```
    if handPtr.isRoyalFlush() {
        handPtr.m_rank = RoyalFlush
```

In case of a straight flush we set the max value to the value of the highest card, which is stored at the beginning of the card list (the card list was been sorted that way when it was created).

```
    } else if handPtr.isStraightFlush() {
        handPtr.m_rank = StraightFlush
        handPtr.m_maxValue = handPtr.m_cardList.Front().Value.(card.Card).Value
```

In case of four of a kind, we set the max value to the value of the four cards, which is stored in the map with the key four.

```
    } else if handPtr.isFourOfAKind() {
        handPtr.m_rank = FourOfAKind
        handPtr.m_maxValue = handPtr.m_map[4].Front().Value.(int)
```

In case of full house, we set the max value to the value of the three cards, even though the pair may hold higher cards.

```
    } else if handPtr.isFullHouse() {
        handPtr.m_rank = FullHouse
        handPtr.m_maxValue = handPtr.m_map[3].Front().Value.(int)
```

In case of flush, we set the rest values to the values of all the cards, since we may have to compare every card with another flush, in case the four highest cards hold the same values.

```
    } else if handPtr.isFlush() {
        handPtr.m_rank = Flush
        handPtr.loadCardValues(handPtr.m_cardList)
```

In case of straight, we set the max value to the value of the highest cards, which stored at the beginning of the card list.

```

    } else if handPtr.isStraight() {
        handPtr.m_rank = Straight
        handPtr.m_maxValue = handPtr.m_cardList.Front().Value.(card.Card).Value
    }

```

In case of three of a kind, we set the max value to the value of the three cards, which is stored in the map with the key three.

```

    } else if handPtr.isThreeOfAKind() {
        handPtr.m_rank = ThreeOfAKind
        handPtr.m_maxValue = handPtr.m_map[3].Front().Value.(int)
    }

```

In case of two pairs we set the max value to the value of the highest pair, and the min value to the value of the lowest pair. Moreover, and add the fifth remaining card to the rest values. The value of the highest pair always comes first in the list, since the cards was sorted in the order when it was created.

```

    } else if handPtr.isTwoPairs() {
        handPtr.m_rank = TwoPairs
        handPtr.m_maxValue = handPtr.m_map[2].Front().Value.(int)
        handPtr.m_minValue = handPtr.m_map[2].Front().Next().Value.(int)
        handPtr.m_restValues = handPtr.m_map[1]
    }

```

In case of one pair we set the max value to the value of the pair, and add the values of the remaining three cards to the rest values.

```

    } else if handPtr.isOnePair() {
        handPtr.m_rank = OnePair
        handPtr.m_maxValue = handPtr.m_map[2].Front().Value.(int)
        handPtr.m_restValues = handPtr.m_map[1]
    }

```

If case of nothing, we save the values of all the cards to the rest values.

```

    } else {
        handPtr.m_rank = Nothing
        handPtr.loadCardValues(handPtr.m_cardList)
    }
}

```

The **containsKeyInMap** method returns true if the map holds the key.

```

func containsKeyInMap(m map[int]*list.List, key int) bool {
    _, exists := m[key]
    return exists
}

```

The **loadCardValues** method loads the values of the list to the rest values.

```

func (handPtr *hand) loadCardValues(values *list.List) {
    handPtr.m_restValues = list.New()

    for iterator := values.Front(); iterator != nil;
        iterator = iterator.Next() {
        handPtr.m_restValues.PushBack(iterator.Value.(card.Card).Value)
    }
}

```

A hand is a royal flush if it is a straight flush where the highest card is an ace.

```

func (handPtr *hand) isRoyalFlush() bool {
    return handPtr.isStraightFlush() &&
        (handPtr.m_cardList.Front().Value.(card.Card).Value == card.Ace)
}

```

A hand is a straight flush if it is a straight and a flush.

```
func (handPtr *hand) isStraightFlush() bool {
    return handPtr.isStraight() && handPtr.isFlush()
}
```

A hand is four of a kind if it holds four cards of the same value, which it does if the map holds a key of value four.

```
func (handPtr *hand) isFourOfAKind() bool {
    return containsKeyInMap(handPtr.m_map, 4)
}
```

A hand is a full house if it is three of a kind and a pair.

```
func (handPtr *hand) isFullHouse() bool {
    return handPtr.isThreeOfAKind() && handPtr.isOnePair();
}
```

A hand is a flush is all the cards hold the same suit. We iterate through the cards, beginning with the second card, and checking if they all have the same suit as the first card.

```
func (handPtr *hand) isFlush() bool {
    firstSuit := handPtr.m_cardList.Front().Value.(card.Card).Suit

    for iterator := handPtr.m_cardList.Front().Next(); iterator != nil;
        iterator = iterator.Next() {
        if iterator.Value.(card.Card).Suit != firstSuit {
            return false
        }
    }

    return true
}
```

A hand is a straight if the difference between the first and last card is four (remember that the cards are sorted in descending order) and there is no set of cards larger than one; that is, there are no two, three, or four cards with the same value.

```
func (handPtr *hand) isStraight() bool {
    firstCard := handPtr.m_cardList.Front().Value.(card.Card)
    lastCard := handPtr.m_cardList.Back().Value.(card.Card)

    return ((firstCard.Value - lastCard.Value) == 4) &&
        (len(handPtr.m_map) == 1) && containsKeyInMap(handPtr.m_map, 1)
}
```

A hand is three of a kind if it holds three cards of the same value, which it does if the map holds a key of value three.

```
func (handPtr *hand) isThreeOfAKind() bool {
    return containsKeyInMap(handPtr.m_map, 3)
}
```

A hand holds two pairs if there are two occurrences of two cards with the same value.

```
func (handPtr *hand) isTwoPairs() bool {
    return containsKeyInMap(handPtr.m_map, 2) && (handPtr.m_map[2].Len() == 2)
}
```

A hand holds one pair if there are one occurrence of two cards with the same value.

```
func (handPtr *hand) isOnePair() bool {
    return containsKeyInMap(handPtr.m_map, 2)
}
```

The **CompareWith** method compares the hand with another hand, and return **Win**, **Tie**, or **Lose**.

```
func (leftHand hand) CompareWith(compareTo ComparableHand) (theResult int){
```

The **compare** variable holds the difference between the two hands and will eventually be used to determine if the left hand wins, ties, or loses over the right hand.

```
    compare := 0
```

We try to convert the **compareTo** argument of the **ComparableHand** interface to the **hand** structure **rightHand**. If the conversion fails, nothing happens, and **Tie** is returned.

```
    rightHand, ok := compareTo.(hand)
    if ok {
```

If the conversion succeeded, we compare the ranks of the hands. If they differ, **compare** is assigned the value of the difference between the left and right hand.

```
        if leftHand.m_rank != rightHand.m_rank {
            compare = leftHand.m_rank - rightHand.m_rank
```

If the hands hold the same rank, we look into their max values. If they differ, **compare** is assigned the value of their difference.

```
        } else if leftHand.m_maxValue != rightHand.m_maxValue {
            compare = leftHand.m_maxValue - rightHand.m_maxValue
```

If the hands hold the same rank and the same max values, we look into their min values. If they differ, **compare** is assigned the value of their difference.

```
        } else if leftHand.m_minValue != rightHand.m_minValue {
            compare = leftHand.m_minValue - rightHand.m_minValue
```

Finally, if the hands hold the same rank as well as max and min values, we look into their rest values, and compare them from the highest to the lowest value. The **compare** variable is assigned the value of their difference, if there in fact is a difference. It is quite possible that there is no difference. For instance, two hands may have flushes with the same values, but different suits.

We iterate through both the rest values, and compare their values. But before that we need to check whether the rest values are not nil, since we may have two royal flushes, in which case all values so far have been equal, but they do not have rest values.

```
        } else if leftHand.m_restValues != nil {
            leftIterator := leftHand.m_restValues.Front()
            rightIterator := rightHand.m_restValues.Front();

            for leftIterator != nil {
                leftValue := leftIterator.Value.(int)
                rightValue := rightIterator.Value.(int)
```

If we find two cards with different values, **compare** is assigned the difference and we break the loop.

```
                if leftValue != rightValue {
                    compare = leftIterator.Value.(int) - rightIterator.Value.(int)
                    break
                }

                leftIterator = leftIterator.Next()
                rightIterator = rightIterator.Next()
            }
        }
```

```
    }
}
```

When we have compared the ranks and values of the hands, we return the final result. If **compare** holds a positive value the left hand has won and we return **Win**, if it holds a negative value the right hand has won and we return **Lose**, and if it is zero we have a tie and we return **Tie**.

```
if compare > 0 {
    return result.Win
} else if compare < 0 {
    return result.Lose
} else {
    return result.Tie
}
}
```

The **String** method return a string representing the hand, which is divided into three parts:

- The cards, written in plain text.
- The rank and max and min values, unless they are zero.
- The map holding the values of the hand.

```
func (theHand hand) String() string {
```

We iterate through the cards and add their text to the cards buffer.

```
cardsBuffer := "{"
for iterator := theHand.m_cardList.Front(); iterator != nil;
    iterator = iterator.Next() {
    if iterator != theHand.m_cardList.Front() {
        cardsBuffer += ", "
    }

    card := iterator.Value.(card.Card)
    cardsBuffer += card.String()
}
cardsBuffer += "}"
```

We add the text of the rank to the rank buffer.

```
rankArray := [...] string {"Nothing", "One Pair", "Two Pairs",
    "Three Of A Kind", "Straight", "Flush", "Full House",
    "Four Of A Kind", "Straight Flush", "Royal Flush"};
rankBuffer := rankArray[theHand.m_rank]
```

We add the max and min values to the rank buffer, if they are not zero.

```
if theHand.m_maxValue != 0 {
    rankBuffer += ", max value " + strconv.Itoa(theHand.m_maxValue)
}

if theHand.m_minValue != 0 {
    rankBuffer += ", min value " + strconv.Itoa(theHand.m_minValue)
}
```

We add the map to the map buffer. We iterate through the map and, for each key, write the key and its associated value list.

```

mapBuffer := "{"
for size, list := range theHand.m_map {
    if len(mapBuffer) > 1 {
        mapBuffer += ", "
    }

    mapBuffer += strconv.Itoa(size) + ": ["

```

For each key, we iterate through its value list and add each value to the map buffer.

```

    for iterator := list.Front(); iterator != nil;
        iterator = iterator.Next() {
        if iterator != list.Front() {
            mapBuffer += ", "
        }

        mapBuffer += strconv.Itoa(iterator.Value.(int))
    }

    mapBuffer += "]"
}
mapBuffer += "}"

```

Finally, we return the card buffer, rank buffer, and map buffer.

```

return cardsBuffer + "\n" + rankBuffer + ", " + mapBuffer
}

```

Error Handling

There are five possible errors:

- Invalid number of cards. There are less or more than five cards in the text describing the hand.
- Invalid length of card text. The text describing a card is less or more than two characters.
- Invalid card value. The card character is not a digit between two and nine, inclusive. Neither is it a character describing ten, jack, queen, king, or ace.
- Invalid card suit. The card suit is not a character representing clubs, diamonds, hearts, or spades.
- Card occurs twice. The same card occurs twice in the hand.

Each of these errors result in a panic call, that can be caught by the calling function.

error/error.go

```

package error

import (
    "fmt"
    "card"
)

type Error struct {
    m_message string
}

func (errorPtr *Error) Message() string {
    return errorPtr.m_message
}

func InvalidNumberOfCards(number int) {
    panic(Error{fmt.Sprintf("Invalid number of cards in hand: %d.", number)})
}

```

```

func InvalidLengthOfCardText(cardText string) {
    panic(Error{fmt.Sprintf("Invalid length of card text: %s.", cardText)})
}

func InvalidCardValue(valueChar string) {
    panic(Error{fmt.Sprintf("Invalid card value: %s.", valueChar)})
}

func InvalidCardSuit(suitChar string) {
    panic(Error{fmt.Sprintf("Invalid card suit: %s.", suitChar)})
}

func CardOccursTwice(card card.Card) {
    panic(Error{fmt.Sprintf("Card occurs twice in the hand: %s.",
        card.String())})
}

```

Result

The result values were given in the instruction. They represent tie, win, and lose between the hands given to the **CompareWith** method.

result/result.go

```

package result

const (
    // Tie represent a `tie` scenario
    Tie = 0

    // Win represent a `win` scenario
    Win = 1

    // Lose represent a `lose` scenario
    Lose = 2
)

```

Main

The main program writes a set of hands to make sure the hands have been correctly read and interpreted.

main.go

```

package main

import (
    "fmt"
    "poker"
    "error"
)

func main() {
    defer func() {
        err, ok := recover().(error.Error)

        if ok {
            fmt.Println(err.Message())
        }
    }()
}

```

```

fmt.Println(poker.NewHand("Th Jh Qh Kh Ah"), "\n") // Royal Flush
fmt.Println(poker.NewHand("Ts Js Qs 9s 8s"), "\n") // Straight Flush
fmt.Println(poker.NewHand("Ts Tc Td 9s Th"), "\n") // Four of a kind
fmt.Println(poker.NewHand("5s 8h 5c 8s 5d"), "\n") // Full House
fmt.Println(poker.NewHand("Kd 8d 4d Td 2d"), "\n") // Flush
fmt.Println(poker.NewHand("5s 8h 4c 6s 7d"), "\n") // Straight
fmt.Println(poker.NewHand("5s 7h 4c 7s 7d"), "\n") // Three of a kind
fmt.Println(poker.NewHand("5s 6h 4c 6s 5d"), "\n") // Two Pairs
fmt.Println(poker.NewHand("5s 7h 4c 7s 8d"), "\n") // One Pair
fmt.Print(poker.NewHand("2s 7h 4c Ts Qd"))          // Nothing
}

```

The execution of the main program produces the following output:

```

C:\Users\Stefan\Documents\Go\src>go run main
{Ace of Hearts, King of Hearts, Queen of Hearts, Jack of Hearts, Ten of Hearts}
Royal Flush, {1: [14, 13, 12, 11, 10]}

{Queen of Spades, Jack of Spades, Ten of Spades, Nine of Spades, Eight of Spades}
Straight Flush, max value 12, {1: [12, 11, 10, 9, 8]}

{Ten of Spades, Ten of Clubs, Ten of Diamonds, Ten of Hearts, Nine of Spades}
Four Of A Kind, max value 10, {4: [10], 1: [9]}

{Eight of Hearts, Eight of Spades, Five of Spades, Five of Clubs, Five of Diamonds}
Full House, max value 5, {2: [8], 3: [5]}

{King of Diamonds, Ten of Diamonds, Eight of Diamonds, Four of Diamonds, Two of Diamonds}
Flush, {1: [13, 10, 8, 4, 2]}

{Eight of Hearts, Seven of Diamonds, Six of Spades, Five of Spades, Four of Clubs}
Straight, max value 8, {1: [8, 7, 6, 5, 4]}

{Seven of Hearts, Seven of Spades, Seven of Diamonds, Five of Spades, Four of Clubs}
Three Of A Kind, max value 7, {3: [7], 1: [5, 4]}

{Six of Hearts, Six of Spades, Five of Spades, Five of Diamonds, Four of Clubs}
Two Pairs, max value 6, min value 5, {2: [6, 5], 1: [4]}

{Eight of Diamonds, Seven of Hearts, Seven of Spades, Five of Spades, Four of Clubs}
One Pair, max value 7, {1: [8, 5, 4], 2: [7]}

{Queen of Diamonds, Ten of Spades, Seven of Hearts, Four of Clubs, Two of Spades}
Nothing, {1: [12, 10, 7, 4, 2]}
C:\Users\Stefan\Documents\Go\src>

```

Test Cases

The first three of the following test cases were given in the instruction. I have added a set of extra test cases.

poker/main_test.go

```

package poker

import (
    "testing"
    "github.com/stretchr/testify/assert"
    "result"
)

```

```

func TestHighCardTie(t *testing.T) {
    hand1 := NewHand("Ks 2h 5c Jd Td") // Nothing
    hand2 := NewHand("Kc 2s 5h Jh Tc") // Nothing
    assert.Equal(t, result.Tie, hand1.CompareWith(hand2))
}

func TestPairWin(t *testing.T) {
    hand1 := NewHand("As 2h 2c Qd Td") // One pair
    hand2 := NewHand("Ac 2s 5h Kh Tc") // Nothing
    assert.Equal(t, result.Win, hand1.CompareWith(hand2))
}

func TestThreeOfAKindLoss(t *testing.T) {
    hand1 := NewHand("As Ts Th Kd Td") // Three of a kind
    hand2 := NewHand("Ac As Ah Ad Tc") // Four of a kind
    assert.Equal(t, result.Lose, hand1.CompareWith(hand2))
}

func TestStraighFlushes(t *testing.T) {

    assert.Equal(t, result.Win, hand1.CompareWith(hand2))
}

```

Note that the first hand wins, since it holds higher threes of a kind, even though the second hand has higher cards.

```

func TestFullHouse(t *testing.T) {
    hand1 := NewHand("Js Jd 8s 8c Jh") // Full house, 3 jacks, 2 eights
    hand2 := NewHand("Th Kd Td Ks Tc") // Full house, 3 tens, 2 kings
    assert.Equal(t, result.Win, hand1.CompareWith(hand2))
}

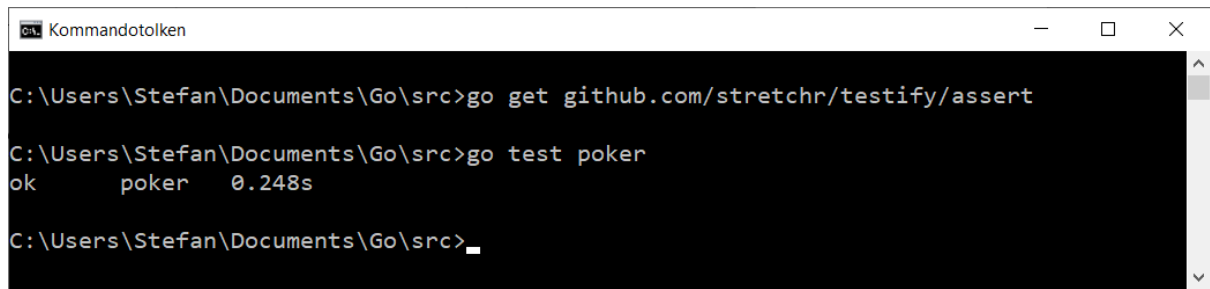

func TestStraigh(t *testing.T) {

    assert.Equal(t, result.Win, hand1.CompareWith(hand2))
}

func TestRoyalFlush(t *testing.T) {

}

```

```
C:\Users\Stefan\Documents\Go\src>go get github.com/stretchr/testify/assert

C:\Users\Stefan\Documents\Go\src>go test poker
ok      poker   0.248s

C:\Users\Stefan\Documents\Go\src>_
```

Conclusions

This has been a very stimulating task, and I feel that I have learned a lot about programming in Go.

Appendix: C# Code

This appendix holds code solving the same problem in C#.

Values.cs

```
namespace Poker {
    enum Value {Jack = 11, Queen, King, Ace};
}
```

Suit.cs

```
namespace Poker {
    public enum Suit {Clubs, Diamonds, Hearts, Spades}
}
```

Rank.cs

```
namespace Poker {
    enum Rank {Nothing, OnePair, TwoPairs, ThreeOfAKind, Straight,
               Flush, FullHouse, FourOfAKind, StraightFlush, RoyalFlush};
}
```

Result.cs

```
namespace Poker {
    public enum Result {Tie, Win, Lose}
}
```

Card.cs

```
